Deep Dive into Android IPC/Binder Framework

Aleksandar (Saša) Gargenta

# Why are you here?

- You want to better understand how Android works
  - Intents, ContentProviders, Messenger
  - Access to system services
  - Life-cycle call-backs
  - Security
- You want to modularize your own business logic across application boundaries via a highly efficient and low-latency IPC framework

- You want to add new system services and would like to learn how to best expose them to your developers
- You just care about IPC and Binder seems unique and interesting
- You don't have anything better to do?

# **Objectives**

- Binder Overview
- IPC
- Advantages of Binder
- Binder vs Intent/ContentProvider/Messenger-based IPC
- Binder Terminology
- Binder Communication and Discovery
- AIDL
- Binder Object Reference Mapping
- Binder by Example
- Async Binder
- Memory Sharing
- Binder Limitations
- Security

Slides and screencast from this class will be posted to: http://mrkn.co/qas0u.

## Who am I?

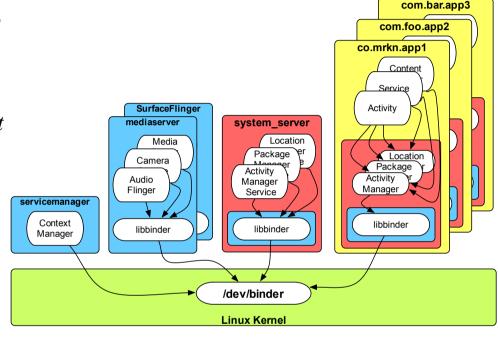

#### Aleksandar Gargenta

- Developer and instructor of Android Internals and Security training at Marakana
- Founder and co-organizer of San Francisco Android User Group (sfandroid.org)
- Founder and co-organizer of San Francisco Java User Group (sfjava.org)
- Co-founder and co-organizer of San Francisco HTML5 User Group (sfhtml5.org)
- Speaker at AnDevCon, AndroidOpen, Android Builders Summit, etc.
- Server-side Java and Linux, since 1997
- Android/embedded Java and Linux, since 2009
- Worked on SMS, WAP Push, MMS, OTA provisioning in previous life
- Follow
  - @agargenta

## What is Binder?

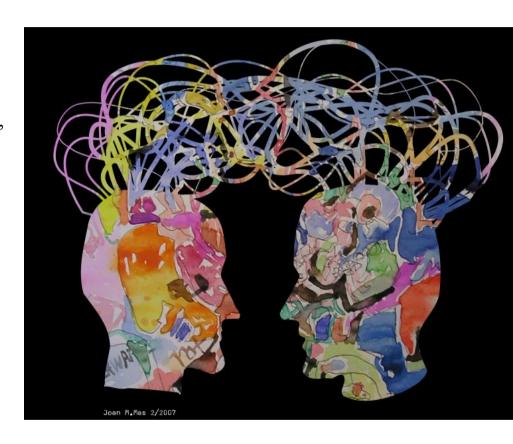

- An IPC/component system for developing object-oriented OS services
  - Not yet another *object-oriented kernel*
  - Instead *an object-oriented operating system environment* that works on traditional kernels, like Linux!
- Essential to Android!
- Comes from OpenBinder
  - Started at Be, Inc. as a key part of the "next generation BeOS" (~ 2001)
  - Acquired by PalmSource
  - First implementation used in Palm Cobalt (micro-kernel based OS)
  - Palm switched to Linux, so Binder ported to Linux, open-sourced (~ 2005)
  - Google hired Dianne Hackborn, a key OpenBinder engineer, to join the Android team
  - ∘ Used as-is for the initial bring-up of Android, but then completely rewritten (~ 2008)
  - OpenBinder no longer maintained long live Binder!

| Focused on scalability, stability, flexibility, low-latency/overhead, easy programming model |  |  |  |  |  |  |

## **IPC**

- Inter-process communication (IPC) is a framework for the exchange of signals and data across multiple processes
- Used for message passing, synchronization, shared memory, and remote procedure calls (RPC)
- Enables information sharing, computational speedup, modularity, convenience, privilege separation, data isolation, stability
  - Each process has its own (sandboxed) address space,
     typically running under a unique system ID
- Many IPC options
  - Files (including memory mapped)
  - Signals
  - Sockets (UNIX domain, TCP/IP)
  - Pipes (including named pipes)
  - Semaphores

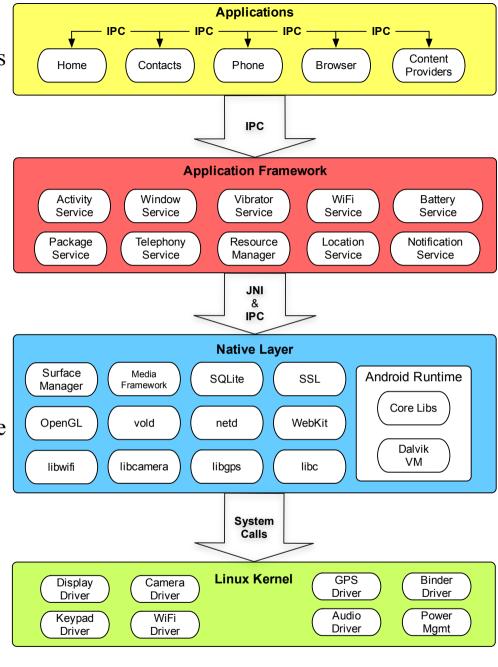

- Shared memory
- Message passing (including queues, message bus)
- Intents, ContentProviders, Messenger
- Binder!

# Why Binder?

- Android apps and system services run **in separate processes** for security, stability, and memory management reasons, but they need to communicate and share data!
  - Security: each process is sandboxed and run under a distinct system identity
  - Stability: if a process misbehaves (e.g. crashes), it does not affect any other processes
  - Memory management: "unneeded" processes are removed to free resources (mainly memory) for new ones
  - In fact, a single Android app can have its components run in separate processes
- IPC to the rescue
  - But we need to avoid overhead of traditional IPC and avoid denial of service issues
- Android's libc (a.k.a. bionic) does not support System V IPCs,
  - No SysV semaphores, shared memory segments, message queues, etc.
  - System V IPC is prone to kernel resource leakage, when a process "forgets" to release shared IPC resources upon termination
  - Buggy, malicious code, or a well-behaved app that is low-memory SIGKILL'ed

- Binder to the rescue!
  - Its built-in reference-counting of "object" references plus death-notification mechanism make it suitable for "hostile" environments (where lowmemorykiller roams)
  - When a binder service is no longer referenced by any clients, its owner is automatically notified that it can dispose of it
- Many other features:
  - "Thread migration" like programming model:
    - Automatic management of thread-pools
    - Methods on remote objects can be invoked as if they were local - the thread appears to "jump" to the other process
    - Synchronous and asynchronous (oneway) invocation model
  - Identifying senders to receivers (via UID/PID) important for security reasons
  - Unique object-mapping across process boundaries
    - A reference to a remote object can be passed to yet another process and can be used as an identifying token

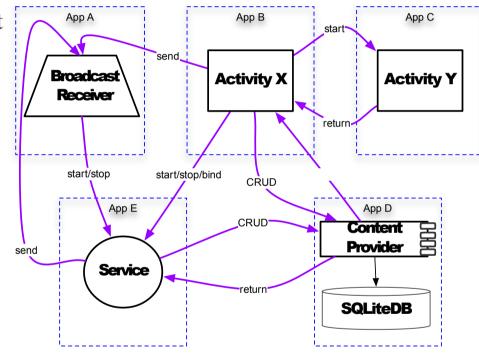

- Ability to send file descriptors across process boundaries
- Simple Android Interface Definition Language (AIDL)
- Built-in support for marshalling many common data-types
- Simplified transaction invocation model via auto-generated proxies and stubs (Java-only)
- Recursion across processes i.e. behaves the same as recursion semantics when calling methods on local objects
- Local execution mode (no IPC/data marshalling) if the client and the service happen to be in the same process

#### • But:

- No support for RPC (local-only)
- Client-service message-based communication not well-suited for streaming
- Not defined by POSIX or any other standard
- Most apps and core system services depend on Binder
  - Most app component life-cycle call-backs (e.g. onResume (), onDestory (), etc.) are invoked by ActivityManagerService via binder
  - Turn off binder, and the entire system grinds to a halt (no display, no audio, no input, no sensors, ...)
  - Unix domain sockets used in some cases (e.g. RILD)

# IPC with Intents and ContentProviders?

- Android supports a simple form of IPC via intents and content providers
- Intent messaging is a framework for asynchronous communication among Android components
  - Those components may run in the same or across different apps (i.e. processes)
  - Enables both point-to-point as well as publish-subscribe messaging domains
  - The intent itself represents a message containing the description of the operation to be performed as well as data to be passed to the recipient(s)
  - Implicit intents enable loosely-coupled APIs

• ContentResolvers communicate synchronously with ContentProviders (typically running in separate apps) via a fixed (CRUD) API

- All android component can act as a senders, and most as receivers
- All communication happens on the Looper (a.k.a. *main*) thread (by default)

#### • But:

- Not really OOP
- Asynchronous-only model for intent-based communication
- Not well-suited for low-latency
- Since the APIs are loosely-defined, prone to run-time errors
- All underlying communication is based on Binder!
- o In fact, Intents and ContentProvider are just a higher-level abstraction of Binder
- Facilitated via system services: ActivityManagerService and PackageManagerService

#### • For example:

src/com/marakana/shopping/UpcLookupActivity.java

```
public class ProductLookupActivity extends Activity {
 private static final int SCAN REQ = 0;
 public void onClick(View view) {
   Intent intent = new Intent("com.google.zxing.client.android.SCAN");
                                                                                  //0
    intent.setPackage("com.google.zxing.client.android");
                                                                                  //0
    intent.putExtra("SCAN MODE", "PRODUCT MODE");
                                                                                  // 2
   super.startActivityForResult(intent, SCAN REQ);
                                                                                  // 6
 @Override
 protected void onActivityResult(int requestCode, int resultCode, Intent data) { // 4
   if (requestCode == SCAN REQ && resultCode == RESULT OK) {
                                                                                  // 6
     String barcode = data.getStringExtra("SCAN RESULT");
                                                                                  // @
     String format = data.getStringExtra("SCAN RESULT FORMAT");
                                                                                  // 6
      super.startActivity(
        new Intent(Intent.ACTION VIEW,
                                                                                  //0
         Uri.parse("http://www.upcdatabase.com/item/" + barcode)));
```

src/com/google/zxing/client/android/CaptureActivity.java:

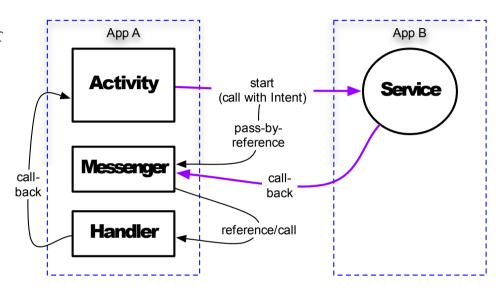

```
mpublic class CaptureActivity extends Activity {
    ...
    private void handleDecodeExternally(Result rawResult, ...) {
        Intent intent = new Intent(getIntent().getAction());
        intent.addFlags(Intent.FLAG_ACTIVITY_CLEAR_WHEN_TASK_RESET);
        intent.putExtra(Intents.Scan.RESULT, rawResult.toString());
        intent.putExtra(Intents.Scan.RESULT_FORMAT,
            rawResult.getBarcodeFormat().toString());
        ...
        super.setResult(Activity.RESULT_OK, intent);
        super.finish();
    }
}
```

- Specify who we want to call
- Specify the input parameter for our call
- Initiate the call asynchronously
- Receive the response via a call-back
- Verify that this is the response we we expecting
- **6** Get the response
- Initiate another IPC request, but don't expect a result
- **8** On the service side, put the result into a new intent
- Send the result back (asynchronously)

## Messenger IPC

- Android's Messenger represents a reference to a Handler that can be sent to a remote process via an Intent
- A reference to the Messenger can be sent via an Intent using the previously mentioned IPC mechanism
- Messages sent by the remote process via the messenger are delivered to the local handler
- Messages are like Intents, in that they can designate the "operation" (aMessage.what) and data (aMessage.getData())
- Still asynchronous, but lower latency/overhead
- Great for efficient call-backs from the service to the client
- Messages are by default handled on the Looper thread
- All underlying communication is still based on Binder!
- For example, this is how we could write a client:

  src/com/marakana/android/download/client/DownloadClientActivity.java:

```
public class DownloadClientActivity extends Activity {
 private static final int CALLBACK MSG = 0;
 @Override
 public void onClick(View view) {
   Intent intent = new Intent(
      "com.marakana.android.download.service.SERVICE");
                                                                           // 0
   ArrayList<Uri> uris = ...
   intent.putExtra("uris", uris);
                                                                           // 2
   Messenger messenger = new Messenger(new ClientHandler(this));
                                                                           // 🔞
   intent.putExtra("callback-messenger", messenger);
                                                                           // 4
   super.startService(intent);
                                                                           // 6
  }
 private static class ClientHandler extends Handler {
   private final WeakReference<DownloadClientActivity> clientRef;
                                                                           // @
   public ClientHandler(DownloadClientActivity client) {
     this.clientRef = new WeakReference<DownloadClientActivity>(client);
   @Override
   public void handleMessage(Message msg) {
                                                                           // 0
      Bundle data = msg.getData();
     DownloadClientActivity client = clientRef.get();
      if (client != null && msg.what == CALLBACK MSG && data != null) {
       Uri completedUri = data.getString("completed-uri");
                                                                           // 8
       // client now knows that completedUri is done
```

- Specify who we want to call (back to using Intents!)
- Specify the input parameter for our call
- Create a messenger over our handler
- Pass the messenger also as an input parameter
- Initiate the call asynchronously
- Our handler remembers a reference to the client
- Receive responses via a call-back on the handler
- Get the response data
- And our service could look as follows:

src/com/marakana/android/download/service/DownloadService.java:

```
public class MessengerDemoService extends IntentService {
 private static final int CALLBACK MSG = 0;
 @Override
 protected void onHandleIntent(Intent intent) {
                                                                            // 0
   ArrayList<Uri> uris = intent.getParcelableArrayListExtra("uris");
                                                                           // 2
   Messenger messenger = intent.getParcelableExtra("callback-messenger"); // 6
   for (Uri uri : uris) {
     // download the uri
      if (messenger != null) {
       Message message = Message.obtain();
                                                                            // 4
       message.what = CALLBACK MSG;
        Bundle data = new Bundle(1);
        data.putParcelable("completed-uri", uri);
                                                                            // 6
       message.setData(data);
                                                                            // 4
       try {
         messenger.send(message);
                                                                            // @
        } catch (RemoteException e) {
        } finally {
          message.recycle();
                                                                            // 4
```

• Handle the request from our client (which could be local or remote)

- Get the request data
- Get the reference to the messenger
- Use Message as a generic envelope for our data
- **6** Set our reply
- Send our reply

# Binder Terminology

#### Binder (Framework)

The overall IPC architecture

#### Binder Driver

The kernel-level driver that fascinates the communication across process boundaries

#### Binder Protocol

Low-level protocol (ioctl-based) used to communicate with the Binder driver

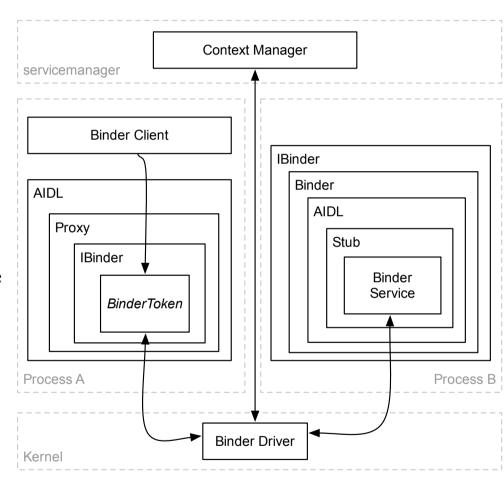

#### IBinder Interface

A well-defined behavior (i.e. methods) that Binder Objects must implement

#### AIDL

Android Interface Definition Language used to describe business operations on an IBinder Interface

## Binder (Object)

A generic implementation of the IBinder interface

#### Binder Token

An abstract 32-bit integer value that uniquely identifies a Binder object across all processes on the system

#### Binder Service

An actual implementation of the Binder (Object) that implements the business operations

#### Binder Client

An object wanting to make use of the behavior offered by a binder service

#### Binder Transaction

An act of invoking an operation (i.e. a method) on a remote Binder object, which may involve sending/receiving data, over the Binder Protocol

#### Parcel

"Container for a message (data and object references) that can be sent through an IBinder." A unit of transactional data - one for the outbound request, and another for the inbound reply

## Marshalling

A procedure for converting higher level applications data structures (i.e. request/response parameters) into parcels for the purposes of embedding them into Binder transactions

### Unmarshalling

A procedure for reconstructing higher-level application data-structures (i.e. request/response parameters) from parcels received through Binder transactions

## Proxy

An implementation of the AIDL interface that un/marshals data and maps method calls to transactions submitted via a wrapped IBinder reference to the Binder object

#### Stub

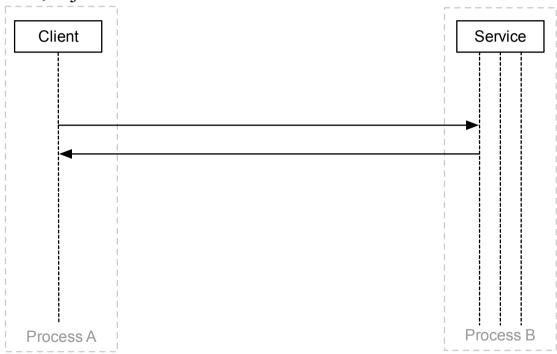

A partial implementation of the AIDL interface that maps transactions to Binder Service method calls while un/marshalling data

### Context Manager (a.k.a. servicemanager)

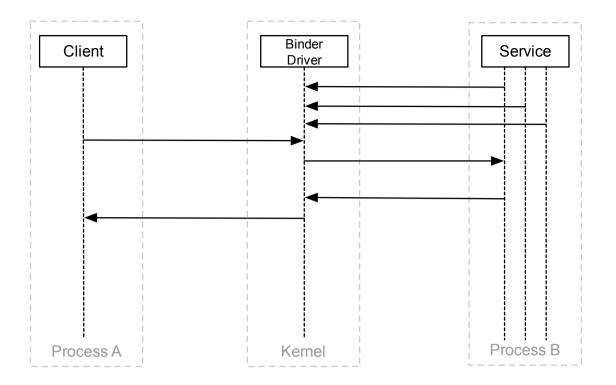

A special Binder Object with a known handle (registered as handle 0) that is used as a registry/lookup service for other Binder Objects ( $name \rightarrow handle$  mapping)

# Binder Communication and Discovery

• As far as the client is concerned, it just wants to *use* the service:

• While processes cannot directly invoke operations (or read/write data) on other processes, the kernel can, so they make use of the Binder driver:

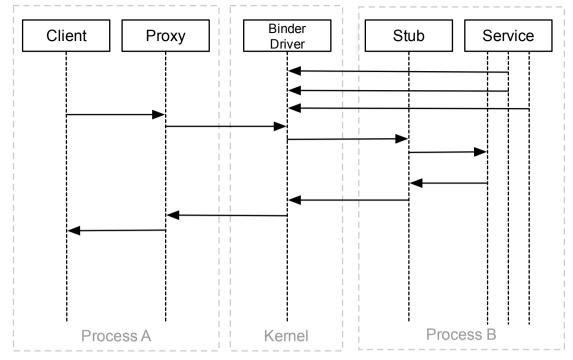

- Since the service may get concurrent requests from multiple clients, it needs to protect (synchronize access to) its mutable state.
- Binder driver is exposed via /dev/binder and offers a relatively simple API based on open, release, poll, mmap, flush, and ioctl operations.
- In fact most communication happens via ioctl (binderFd, BINDER\_WRITE\_READ, &bwd), where bwd is defined as:

```
struct binder_write_read {
    signed long write_size; /* bytes to write */
    signed long write_consumed; /* bytes consumed by driver */
    unsigned long write_buffer;
    signed long read_size; /* bytes to read */
    signed long read_consumed; /* bytes consumed by driver */
    unsigned long read_buffer;
};
```

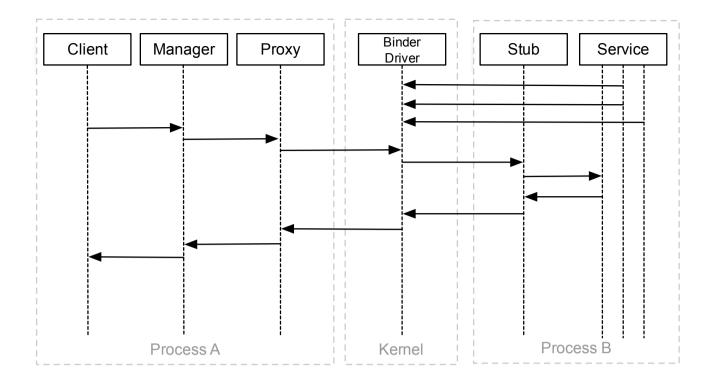

- The write buffer contains a series of commands for the driver to perform
  - Book-keeping commands, e.g. inc/decrement binder object references, request/clear death notification, etc.
  - A command requiring a response, like BC\_TRANSACTION
- Upon returning, the read buffer will contain commands for the user-space to perform
  - Same book-keeping commands
  - A command requesting processing of the response (i.e. BC\_REPLY) or a request to perform a nested (recursive) operation
- Clients communicate with services via transactions, which contain a binder token, code of the method to execute, raw data buffer, and sender PID/UID (added by the driver)
- Most-low-level operations and data structures (i.e. Parcel) are abstracted by libbinder (at the native level), which is what the clients and services use.
- Except that clients and services don't want to know anything about the Binder protocol and libbinder, so they

make use of proxies and stubs:

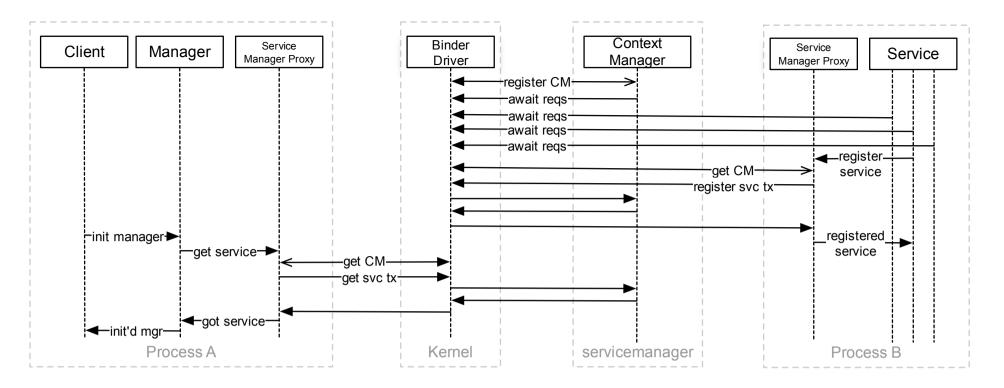

Java-based proxies and stubs can be automatically generated by aidl tool for services described with AIDL.

• In fact, most clients don't even want to know that they are using IPC, never mind Binder, or proxies, so they count on *managers* to abstract all of that complexity for them:

This is in particular true for system services, which typically expose only a subset of their APIs to the clients via their managers.

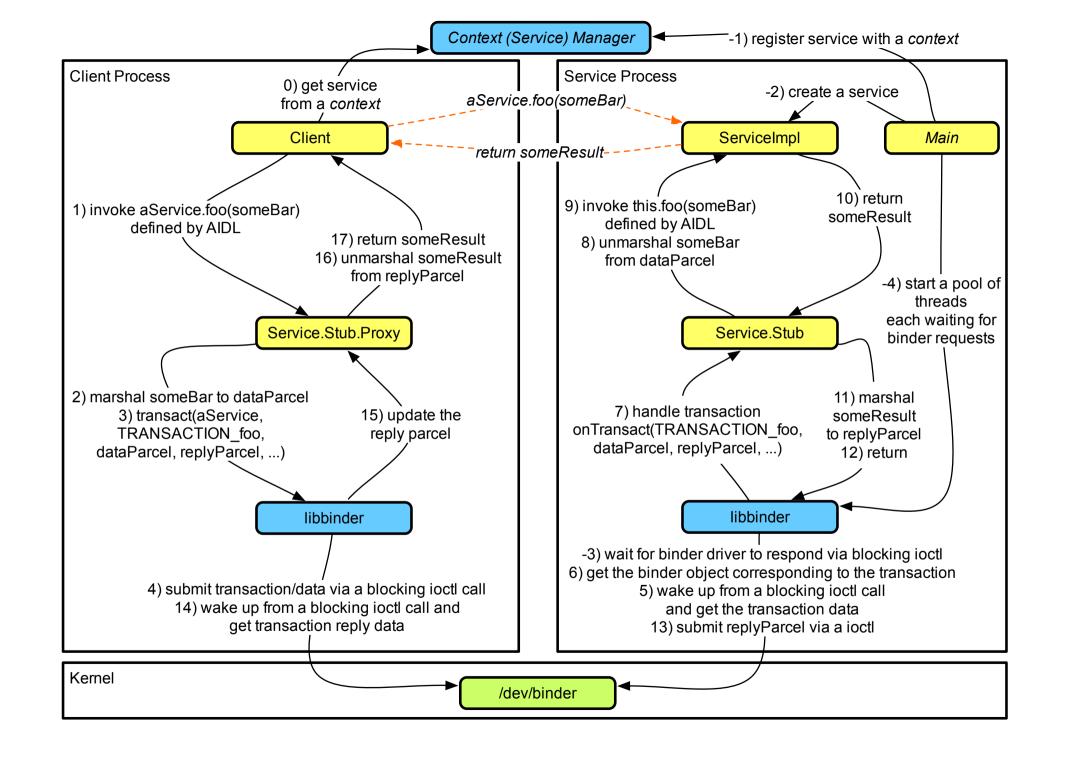

• But how does the client get a handle to the service it wants to talk to? Just ask the servicemanager (Binder's CONTEXT\_MGR), and hope that the service has already registered with it:

- For security/sanity reasons, the binder driver will only accept a single/one-time CONTEXT\_MGR registration, which is why servicemanager is among the first services to start on Android.
- 7 To get a list of services currently registered with servicemanager, run:

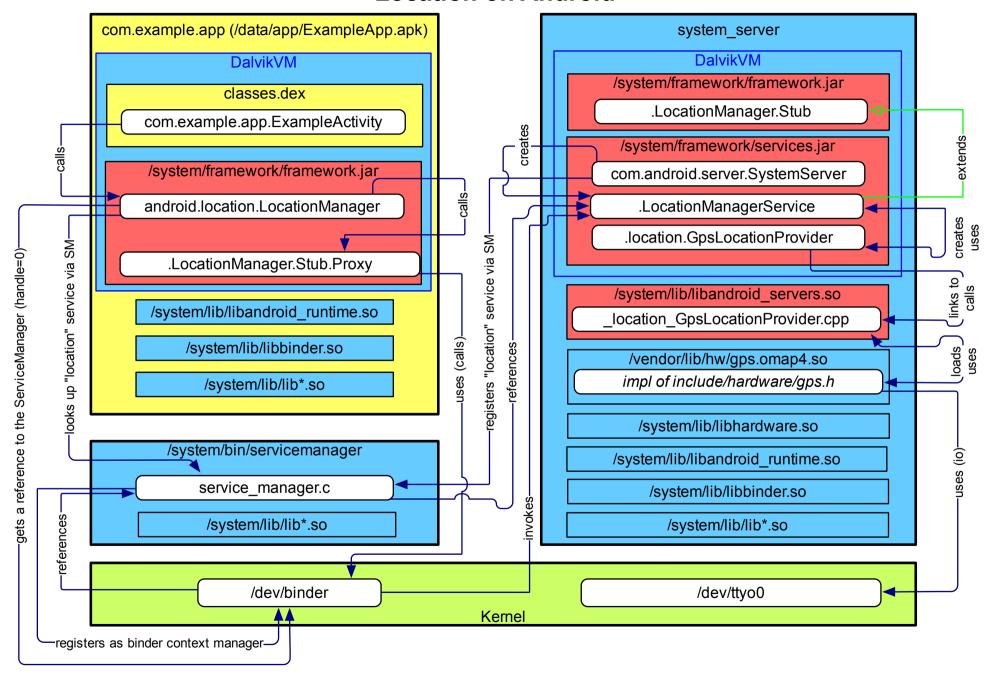

```
$ adb shell service list
Found 71 services:
0 sip: [android.net.sip.ISipService]
1 phone: [com.android.internal.telephony.ITelephony]
...
20 location: [android.location.ILocationManager]
...
55 activity: [android.app.IActivityManager]
56 package: [android.content.pm.IPackageManager]
...
67 SurfaceFlinger: [android.ui.ISurfaceComposer]
68 media.camera: [android.hardware.ICameraService]
69 media.player: [android.media.IMediaPlayerService]
70 media.audio_flinger: [android.media.IAudioFlinger]
```

• Another way to look at it:

## **Location Service: An Example**

#### **Location on Android**

## **AIDL**

- Android Interface Definition Language is a Android-specific language for defining Binder-based service interfaces
- AIDL follows Java-like interface syntax and allows us to declare our "business" methods
- Each Binder-based service is defined in a separate .aidl file, typically named IFOOService.aidl, and saved in the src/directory

src/com/example/app/IFooService.aidl

```
package com.example.app;
import com.example.app.Bar;
interface IFooService {
  void save(inout Bar bar);
  Bar getById(int id);
  void delete(in Bar bar);
  List<Bar> getAll();
}
```

• The aidl build tool (part of Android SDK) is used to extract a real Java interface (along with a Stub providing Android's android.os.IBinder) from each .aidl file and place it into our gen/ directory

gen/com/example/app/IFooService.java

```
package com.example.app;
public interface IFooService extends android.os.IInterface
```

```
public static abstract class Stub extends android.os.Binder
    implements com.example.app.IFooService {
   public static com.example.app.IFooService asInterface(
      android.os.IBinder obj) {
     return new com.example.app.IFooService.Stub.Proxy(obj);
   public boolean onTransact(int code, android.os.Parcel data, android.os.Parcel reply, int flags) throws
android.os.RemoteException {
      switch (code) {
        case TRANSACTION save: {
          com.example.app.Bar arg0;
          arg0 = com.example.app.Bar.CREATOR.createFromParcel(data);
         this.save( arg0);
   private static class Proxy implements com.example.app.IFooService {
      private android.os.IBinder mRemote;
      public void save(com.example.app.Bar bar) throws android.os.RemoteException {
```

```
android.os.Parcel _data = android.os.Parcel.obtain();
...
  bar.writeToParcel(_data, 0);
...
  mRemote.transact(Stub.TRANSACTION_save, _data, _reply, 0);
...
  }
}

void save(com.example.app.Bar bar) throws android.os.RemoteException;
com.example.app.Bar getById(int id) throws android.os.RemoteException;
void delete(com.example.app.Bar bar) throws android.os.RemoteException;
java.util.List<Bar> getAll() throws android.os.RemoteException;
}
```

Eclipse ADT automatically calls  $\verb|aidl|$  for each  $\verb|.aidl|$  file that it finds in our  $\verb|src|$  directory

- AIDL supports the following types:
  - o null
  - o boolean, boolean[], byte, byte[], char[], int, int[], long, long[], float, float[],
     double, double[]
  - java.lang.CharSequence, java.lang.String (sent as UTF-16)
  - java.io.FileDescriptor transferred as a dup of the original file descriptor (points to the same underlying stream and position)
  - java.io.Serializable not efficient (too verbose)

- java.util.Map<String, Object> of supported types (always reconstructed as java.util.HashMap)
- android.os.Bundle a specialized Map-wrapper that only accepts AIDL-supported data types
- java.util.List of supported types (always reconstructed as java.util.ArrayList)
- java.lang.Object[] of supported types (including primitive wrappers)
- android.util.SparseArray, android.util.SparseBooleanArray
- o android.os.IBinder, android.os.IInterface transferred by (globally unique) reference (as a "strong binder", a.k.a. handle) that can be used to call-back into the sender
- android.os.Parcelable allowing for custom types: src/com/example/app/Bar.java

```
package com.example.app;
import android.os.Parcel;
import android.os.Parcelable;

public class Bar implements Parcelable {
  private int id;
  private String data;

public Bar(int id, String data) {
    this.id = id;
    this.data = data;
}

// getters and setters omitted
```

```
public void writeToParcel(Parcel parcel, int flags) {
  parcel.writeInt(this.id);
  parcel.writeString(this.data);
public void readFromParcel(Parcel parcel) {
  this.id = parcel.readInt();
  this.data = parcel.readString();
public static final Parcelable.Creator<Bar> CREATOR = new Parcelable.Creator<Bar>() {
  public Bar createFromParcel(Parcel parcel) {
    return new Bar(parcel.readInt(), parcel.readString());
  public Bar[] newArray(int size) {
    return new Bar[size];
};
```

Here, the public void readFromParcel (Parcel) method is not defined by the Parcelable interface. Instead, it would be required here because Bar is considered mutable - i.e. we expect the remote side to be able to change it in void save (inout Bar bar) method.

Similarly, public static final Parcelable. Creator < Bar > CREATOR field is also not defined by the Parcelable interface (obviously). It reconstructs Bar from \_data parcel in save transaction, and from reply parcel in getById operation.

■ These custom classes have to be declared in their own (simplified) .aidl files <code>src/com/example/app/Bar.aidl</code>

```
package com.example.app;
parcelable Bar;
```

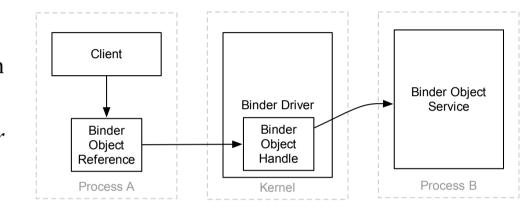

AIDL-interfaces have to import parcelable custom classes even if they are in the same package. In the case of the previous example, src/com/example/app/IFooService.aidl would have to import com.example.app.Bar; if it makes any references to com.example.app.Bar even though they are in the same package.

- AIDL-defined methods can take zero or more parameters, and must return a value or void
- All non-primitive parameters require a *directional tag* indicating which way the data goes: one of: in, out, or inout
  - Direction for primitives is always in (can be omitted)
  - The direction tag tells binder when to marshal the data, so its use has direct consequences on performance
- All .aidl comments are copied over to the generated Java interface (except for comments before the import and package statements).
- Only the following exceptions are implicitly supported: SecurityException, BadParcelableException, IllegalArgumentException, NullPointerException, and IllegalStateException

#### Binder Object Reference Mapping Across Process Boundaries

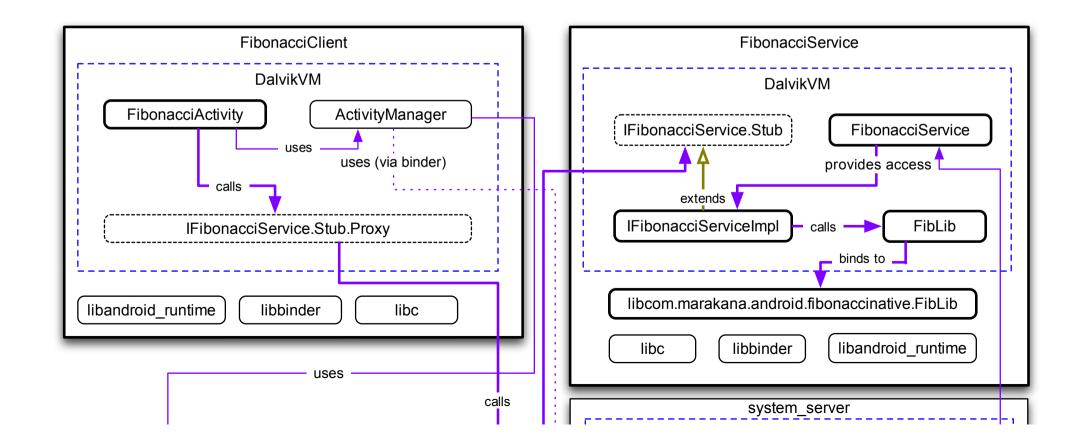

- A binder object reference is one of the following
  - An actual virtual *memory address* to a binder object in the *same process*
  - An abstract 32-bit *handle* to a binder object in *another process*

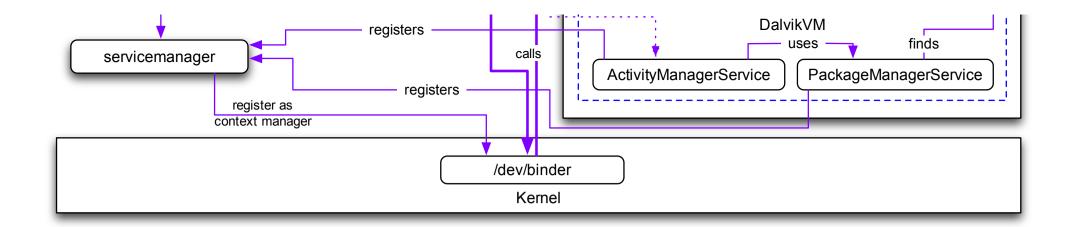

- On every transaction, the binder driver automatically maps local addresses to remote binder handles and remote binder handles to local addresses
- This mapping is done on:
  - Targets of binder transactions
  - IBinder object references shared across process boundaries as a parameter or a return value (embedded in transaction data)
- For this to work
  - The driver maintains mappings of local addresses and remote handles between processes (as a binary-tree per

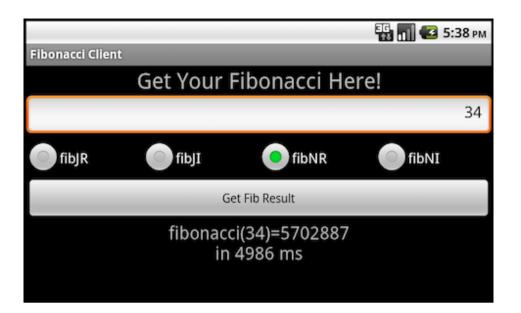

- process) so that it can perform this translation
- References embedded in transaction data are discovered based on offsets that the client provides when it submits its transaction and then rewritten in-place
- The binder driver does not know anything about binder objects that have never been shared with a remote process
  - o Once a new binder object reference is found in a transaction, it is remembered by binder
  - o Any time that reference is shared with another process, its reference count is incremented
  - Reference count is decremented either explicitly or automatically, when the process dies
  - When a reference is no longer needed, its owner is notified that it can be released, and binder removes its mapping

# Building a Binder-based Service and Client by Example

- To demonstrate a Binder-based service and client (based on Fibonacci), we'll create three separate projects:
  - 1. FibonacciCommon library project to define our AIDL interface as well as custom types for parameters and return values
  - 2. FibonacciService project where we implement our AIDL interface and expose it to the clients
  - 3. FibonacciClient project where we connect to our AIDL-defined service and use it
- The code is available
  - As a ZIP archive: https://github.com/marakana/FibonacciBinderDemo/zipball/master
  - By Git: git clone https://github.com/marakana/FibonacciBinderDemo.git
- The UI will roughly look like this when done:

# FibonacciCommon - Define AIDL Interface and Custom Types

- We start by creating a new Android (library) project, which will host the common API files (an AIDL interface as well as custom types for parameters and return values) shared by the service and its clients
  - Project Name: FibonacciCommon
  - Build Target: Android 2.2 (API 8) or later
  - Package Name: com.marakana.android.fibonaccicommon
  - Min SDK Version: 8 or higher
  - No need to specify Application name or an activity
- To turn this into a *library project* we need to access project properties → Android → Library and check Is Library
  - We could also manually add android.library=true to FibonacciCommon/default.properties and refresh the project
- Since library projects are never turned into actual applications (APKs)
  - We can simplify our manifest file:

    FibonacciCommon/AndroidManifest.xml

```
<?xml version="1.0" encoding="utf-8"?>
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
  package="com.marakana.android.fibonaccicommon" android:versionCode="1"
  android:versionName="1.0">
</manifest>
```

- And we can remove everything from FibonacciCommon/res/directory (e.g. rm -fr FibonacciCommon/res/\*)
- We are now ready to create our AIDL interface

FibonacciCommon/src/com/marakana/android/fibonaccicommon/IFibonacciService.aidl

```
package com.marakana.android.fibonaccicommon;

import com.marakana.android.fibonaccicommon.FibonacciRequest;
import com.marakana.android.fibonaccicommon.FibonacciResponse;

interface IFibonacciService {
    long fibJR(in long n);
    long fibJI(in long n);
    long fibNR(in long n);
    long fibNI(in long n);
    FibonacciResponse fib(in FibonacciRequest request);
}
```

• Our interface clearly depends on two custom Java types, which we have to not only implement in Java, but define in their own addl files

FibonacciCommon/src/com/marakana/android/fibonaccicommon/FibonacciRequest.java

```
package com.marakana.android.fibonaccicommon;
import android.os.Parcel;
import android.os.Parcelable;
public class FibonacciRequest implements Parcelable {
 public static enum Type {
   RECURSIVE JAVA, ITERATIVE JAVA, RECURSIVE NATIVE, ITERATIVE NATIVE
  }
 private final long n;
 private final Type type;
 public FibonacciRequest(long n, Type type) {
   this.n = n;
   if (type == null) {
     throw new NullPointerException("Type must not be null");
   this.type = type;
 public long getN() {
   return n;
 public Type getType() {
   return type;
```

```
public int describeContents() {
  return 0;
public void writeToParcel(Parcel parcel, int flags) {
  parcel.writeLong(this.n);
  parcel.writeInt(this.type.ordinal());
public static final Parcelable.Creator<FibonacciRequest> CREATOR = new Parcelable.Creator<FibonacciRequest>()
  public FibonacciRequest createFromParcel(Parcel in) {
    long n = in.readLong();
    Type type = Type.values()[in.readInt()];
    return new FibonacciRequest(n, type);
  public FibonacciRequest[] newArray(int size) {
    return new FibonacciRequest[size];
};
```

FibonacciCommon/src/com/marakana/android/fibonaccicommon/FibonacciRequest.aidl

```
package com.marakana.android.fibonaccicommon;
parcelable FibonacciRequest;
```

FibonacciCommon/src/com/marakana/android/fibonaccicommon/FibonacciResponse.java

```
package com.marakana.android.fibonaccicommon;
```

```
import android.os.Parcel;
import android.os.Parcelable;
public class FibonacciResponse implements Parcelable {
 private final long result;
 private final long timeInMillis;
 public FibonacciResponse(long result, long timeInMillis) {
   this.result = result;
   this.timeInMillis = timeInMillis;
  }
 public long getResult() {
   return result;
  }
 public long getTimeInMillis() {
   return timeInMillis;
 public int describeContents() {
   return 0;
 public void writeToParcel(Parcel parcel, int flags) {
   parcel.writeLong(this.result);
   parcel.writeLong(this.timeInMillis);
```

```
public static final Parcelable.Creator<FibonacciResponse> CREATOR = new Parcelable.Creator<FibonacciResponse>
() {
    public FibonacciResponse createFromParcel(Parcel in) {
        return new FibonacciResponse(in.readLong(), in.readLong());
    }
    public FibonacciResponse[] newArray(int size) {
        return new FibonacciResponse[size];
    }
};
```

FibonacciCommon/src/com/marakana/android/fibonaccicommon/FibonacciResponse.aidl

```
package com.marakana.android.fibonaccicommon;
parcelable FibonacciResponse;
```

• Finally we are now ready to take a look at our generated Java interface

FibonacciCommon/gen/com/marakana/android/fibonaccicommon/IFibonacciService.java

```
package com.marakana.android.fibonaccicommon;
public interface IFibonacciService extends android.os.IInterface
   public static abstract class Stub extends android.os.Binder
        implements com.marakana.android.fibonacci.IFibonacciService {
        public static com.marakana.android.fibonacci.IFibonacciService asInterface(
            android.os.IBinder obj) {
        public android.os.IBinder asBinder() {
            return this;
   public long fibJR(long n) throws android.os.RemoteException;
   public long fibJI(long n) throws android.os.RemoteException;
   public long fibNR(long n) throws android.os.RemoteException;
   public long fibNI(long n) throws android.os.RemoteException;
    public com.marakana.android.fibonaccicommon.FibonacciResponse fib(
        com.marakana.android.fibonaccicommon.FibonacciRequest request)
       throws android.os.RemoteException;
```

# FibonacciService - Implement AIDL Interface and Expose It To Our Clients

- We start by creating a new Android project, which will host the our AIDL Service implementation as well as provide a mechanism to access (i.e. bind to) our service implementation
  - Project Name: FibonacciService
  - Build Target: Android 2.2 (API 8) or later
  - Package Name: com.marakana.android.fibonacciservice
  - Application name: Fibonacci Service
  - Min SDK Version: 8 or higher
  - No need to specify an Android activity
- We need to link this project to the FibonacciCommon in order to be able to access the common APIs: project properties → Android → Library → Add... → FibonacciCommon
  - As the result, FibonacciService/default.properties now has android.library.reference.1=../FibonacciCommon and FibonacciService/.classpath and FibonacciService/.project also link to FibonacciCommon

- Our service will make use of the com.marakana.android.fibonaccinative.FibLib, which provides the actual implementation of the Fibonacci algorithms
- We copy (or move) this Java class (as well as the jni/implementation) from the FibonacciNative project
  - Don't forget to run ndk-build under FibonacciService/ in order to generate the required native library
- We are now ready to implement our AIDL-defined interface by extending from the auto-generated com.marakana.android.fibonaccicommon.IFibonacciService.Stub (which in turn extends from android.os.Binder)

FibonacciService/src/com/marakana/android/fibonacciservice/IFibonacciServiceImpl.java

```
package com.marakana.android.fibonacciservice;
import android.os.SystemClock;
import android.util.Log;
import com.marakana.android.fibonaccicommon.FibonacciRequest;
import com.marakana.android.fibonaccicommon.FibonacciResponse;
import com.marakana.android.fibonaccicommon.IFibonacciService;
import com.marakana.android.fibonaccinative.FibLib;
public class IFibonacciServiceImpl extends IFibonacciService.Stub {
 private static final String TAG = "IFibonacciServiceImpl";
 public long fibJI(long n) {
    Log.d(TAG, String.format("fibJI(%d)", n));
   return FibLib.fibJI(n);
```

```
public long fibJR(long n) {
  Log.d(TAG, String.format("fibJR(%d)", n));
  return FibLib.fibJR(n);
public long fibNI(long n) {
  Log.d(TAG, String.format("fibNI(%d)", n));
  return FibLib.fibNI(n);
public long fibNR(long n) {
  Log.d(TAG, String.format("fibNR(%d)", n));
  return FibLib.fibNR(n);
public FibonacciResponse fib(FibonacciRequest request) {
  Log.d(TAG,
      String.format("fib(%d, %s)", request.getN(), request.getType()));
  long timeInMillis = SystemClock.uptimeMillis();
  long result;
  switch (request.getType()) {
  case ITERATIVE JAVA:
    result = this.fibJI(request.getN());
    break;
  case RECURSIVE JAVA:
    result = this.fibJR(request.getN());
    break;
  case ITERATIVE NATIVE:
    result = this.fibNI(request.getN());
    break;
  case RECURSIVE NATIVE:
```

```
result = this.fibNR(request.getN());
    break;
default:
    return null;
}
timeInMillis = SystemClock.uptimeMillis() - timeInMillis;
return new FibonacciResponse(result, timeInMillis);
}
```

### **Expose our AIDL-defined Service Implementation to Clients**

- In order for clients (callers) to use our service, they first need to bind to it.
- But in order for them to bind to it, we first need to expose it via our own android.app.Service's onBind(Intent) implementation

FibonacciService/src/com/marakana/android/fibonacciservice/FibonacciService.java

```
package com.marakana.android.fibonacciservice;
import android.app.Service;
import android.content.Intent;
import android.os.IBinder;
import android.util.Log;
public class FibonacciService extends Service { // 0
 private static final String TAG = "FibonacciService";
 private IFibonacciServiceImpl service; // @
 @Override
 public void onCreate() {
    super.onCreate();
   this.service = new IFibonacciServiceImpl(); // @
   Log.d(TAG, "onCreate()'ed"); // 6
```

```
@Override
public IBinder onBind(Intent intent) {
  Log.d(TAG, "onBind()'ed"); // 6
  return this.service; // 4
@Override
public boolean onUnbind(Intent intent) {
  Log.d(TAG, "onUnbind()'ed"); // 6
  return super.onUnbind(intent);
@Override
public void onDestroy() {
  Log.d(TAG, "onDestroy()'ed");
  this.service = null;
  super.onDestroy();
```

- We create yet another "service" object by extending from android.app.Service. The purpose of FibonacciService object is to provide access to our Binder-based IFibonacciServiceImpl object.
- Here we simply declare a local reference to IFibonacciServiceImpl, which will act as a singleton (i.e. all clients will share a single instance). Since our IFibonacciServiceImpl does not require any special initialization, we could instantiate it at this point, but we choose to delay this until the onCreate() method.
- Now we instantiate our IFibonacciServiceImpl that we'll be providing to our clients (in the onBind(Intent) method). If our IFibonacciServiceImpl required access to the Context (which it

- doesn't) we could pass a reference to this (i.e. android.app.Service, which implements android.content.Context) at this point. Many Binder-based services use Context in order to access other platform functionality.
- This is where we provide access to our IFibonacciServiceImpl object to our clients. By design, we chose to have only one instance of IFibonacciServiceImpl (so all clients share it) but we could also provide each client with their own instance of IFibonacciServiceImpl.
- We just add some logging calls to make it easy to track the life-cycle of our service.
- Finally, we register our Fibonacci Service in our Android Manifest.xml, so that clients can find it Fibonacci Service / Android Manifest.xml

• The name of this action is arbitrary, but it is a common convention to use the fully-qualified name of our AIDL-derived interface.

### FibonacciClient - Using AIDL-defined Binder-based Services

- We start by creating a new Android project, which will server as the client of the AIDL Service we previously implemented
  - Project Name: FibonacciClient
  - Build Target: Android 2.2 (API 8) or later
  - Package Name: com.marakana.android.fibonacciclient
  - Application name: Fibonacci Client
  - Create activity: FibonacciActivity
    - We'll repurpose most of this activity's code from FibonacciNative
  - Min SDK Version: 8 or higher
- We need to link this project to the FibonacciCommon in order to be able to access the common APIs: project properties → Android → Library → Add... → FibonacciCommon
  - As the result, FibonacciClient/default.properties now has android.library.reference.1=../FibonacciCommon and FibonacciClient/.classpath and FibonacciClient/.project also link to

#### FibonacciCommon

- As an alternative, we could've avoided creating FibonacciCommon in the first place
  - FibonacciService and FibonacciClient could have each had a copy of:

    IFibonacciService.aidl, FibonacciRequest.aidl, FibonacciResponse.aidl,

    FibonacciResult.java, and FibonacciResponse.java++
  - But we don't like duplicating source code (even though the binaries do get duplicated at runtime)
- Our client will make use of the string resources and layout definition from FibonacciNative application FibonacciClient/res/values/strings.xml

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"</pre>
  android:orientation="vertical" android:layout width="fill parent"
 android:layout height="fill parent">
 <TextView android:text="@string/hello" android:layout height="wrap content"</pre>
    android:layout width="fill parent" android:textSize="25sp" android:gravity="center"/>
 <EditText android:layout height="wrap content"</pre>
    android:layout width="match parent" android:id="@+id/input"
    android:hint="@string/input hint" android:inputType="number"
    android:gravity="right" />
 <RadioGroup android:orientation="horizontal"</pre>
    android:layout width="match parent" android:id="@+id/type"
    android:layout height="wrap content">
    <RadioButton android:layout height="wrap content"</pre>
      android:checked="true" android:id="@+id/type fib jr" android:text="@string/type fib jr"
      android:layout width="match parent" android:layout weight="1" />
    <RadioButton android:layout height="wrap content"</pre>
      android:id="@+id/type fib ji" android:text="@string/type fib ji"
      android:layout width="match parent" android:layout weight="1" />
    <RadioButton android:layout height="wrap content"</pre>
      android:id="@+id/type_fib_nr" android:text="@string/type_fib_nr"
      android:layout width="match parent" android:layout weight="1" />
    <RadioButton android:layout height="wrap content"</pre>
      android:id="@+id/type fib ni" android:text="@string/type fib ni"
      android:layout width="match parent" android:layout weight="1" />
 </RadioGroup>
 <Button android:text="@string/button text" android:id="@+id/button"</pre>
    android:layout width="match parent" android:layout height="wrap content" />
 <TextView android:id="@+id/output" android:layout width="match parent"</pre>
    android:layout_height="match_parent" android:textSize="20sp" android:gravity="center|top"/>
</LinearLayout>
```

#### • We are now ready to implement our client

FibonacciClient/src/com/marakana/android/fibonacciclient/FibonacciActivity.java

```
package com.marakana.android.fibonacciclient;
import android.app.Activity;
import android.app.ProgressDialog;
import android.content.ComponentName;
import android.content.Intent;
import android.content.ServiceConnection;
import android.os.AsyncTask;
import android.os.Bundle;
import android.os.IBinder;
import android.os.RemoteException;
import android.os.SystemClock;
import android.text.TextUtils;
import android.util.Log;
import android.view.View;
import android.view.View.OnClickListener;
import android.widget.Button;
import android.widget.EditText;
import android.widget.RadioGroup;
import android.widget.TextView;
import android.widget.Toast;
import com.marakana.android.fibonaccicommon.FibonacciRequest;
import com.marakana.android.fibonaccicommon.FibonacciResponse;
import com.marakana.android.fibonaccicommon.IFibonacciService;
public class FibonacciActivity extends Activity implements OnClickListener,
   ServiceConnection {
```

```
private static final String TAG = "FibonacciActivity";
private EditText input; // our input n
private Button button; // trigger for fibonacci calcualtion
private RadioGroup type; // fibonacci implementation type
private TextView output; // destination for fibonacci result
private IFibonacciService service; // reference to our service
@Override
public void onCreate(Bundle savedInstanceState) {
  super.onCreate(savedInstanceState);
  super.setContentView(R.layout.main);
  // connect to our UI elements
  this.input = (EditText) super.findViewById(R.id.input);
  this.button = (Button) super.findViewById(R.id.button);
  this.type = (RadioGroup) super.findViewById(R.id.type);
  this.output = (TextView) super.findViewById(R.id.output);
  // request button click call-backs via onClick(View) method
  this.button.setOnClickListener(this);
  // the button will be enabled once we connect to the service
  this.button.setEnabled(false);
}
@Override
protected void onResume() {
  Log.d(TAG, "onResume()'ed");
  super.onResume();
```

```
// Bind to our FibonacciService service, by Looking it up by its name
  // and passing ourselves as the ServiceConnection object
  // We'll get the actual IFibonacciService via a callback to
  // onServiceConnected() below
  if (!super.bindService(new Intent(IFibonacciService.class.getName()),
      this, BIND AUTO CREATE)) {
    Log.w(TAG, "Failed to bind to service");
@Override
protected void onPause() {
  Log.d(TAG, "onPause()'ed");
  super.onPause();
  // No need to keep the service bound (and alive) any longer than
  // necessary
  super.unbindService(this);
public void onServiceConnected(ComponentName name, IBinder service) {
  Log.d(TAG, "onServiceConnected()'ed to " + name);
  // finally we can get to our IFibonacciService
  this.service = IFibonacciService.Stub.asInterface(service);
  // enable the button, because the IFibonacciService is initialized
  this.button.setEnabled(true);
public void onServiceDisconnected(ComponentName name) {
  Log.d(TAG, "onServiceDisconnected()'ed to " + name);
  // our IFibonacciService service is no longer connected
  this.service = null;
  // disabled the button, since we cannot use IFibonacciService
```

```
this.button.setEnabled(false);
// handle button clicks
public void onClick(View view) {
  // parse n from input (or report errors)
  final long n;
  String s = this.input.getText().toString();
  if (TextUtils.isEmpty(s)) {
    return;
  try {
    n = Long.parseLong(s);
  } catch (NumberFormatException e) {
    this.input.setError(super.getText(R.string.input error));
    return;
  // build the request object
  final FibonacciRequest.Type type;
  switch (FibonacciActivity.this.type.getCheckedRadioButtonId()) {
  case R.id.type fib jr:
    type = FibonacciRequest.Type.RECURSIVE JAVA;
    break;
  case R.id.type fib ji:
    type = FibonacciRequest.Type.ITERATIVE JAVA;
    break;
  case R.id.type fib nr:
    type = FibonacciRequest.Type.RECURSIVE NATIVE;
    break;
  case R.id.type_fib_ni:
    type = FibonacciRequest.Type.ITERATIVE NATIVE;
```

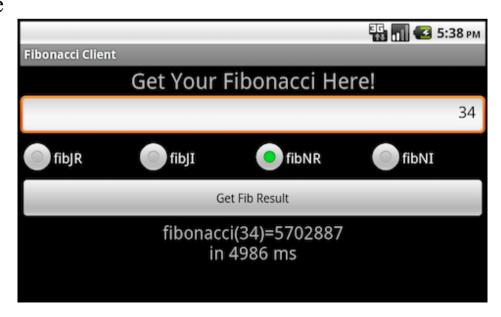

```
break;
default:
  return;
final FibonacciRequest request = new FibonacciRequest(n, type);
// showing the user that the calculation is in progress
final ProgressDialog dialog = ProgressDialog.show(this, "",
    super.getText(R.string.progress text), true);
// since the calculation can take a long time, we do it in a separate
// thread to avoid blocking the UI
new AsyncTask<Void, Void, String>() {
  @Override
  protected String doInBackground(Void... params) {
    // this method runs in a background thread
    try {
      long totalTime = SystemClock.uptimeMillis();
      FibonacciResponse response = FibonacciActivity.this.service
          .fib(request);
      totalTime = SystemClock.uptimeMillis() - totalTime;
      // generate the result
      return String.format(
          "fibonacci(%d)=%d\nin %d ms\n(+ %d ms)", n,
          response.getResult(), response.getTimeInMillis(),
          totalTime - response.getTimeInMillis());
    } catch (RemoteException e) {
      Log.wtf(TAG, "Failed to communicate with the service", e);
      return null;
```

We should avoid having an implicit (but strong) reference from our AsyncTask to our activity. Here we took a shortcut for brevity reasons.

• Our activity should already be registered in our AndroidManifest.xml file FibonacciClient/AndroidManifest.xml

And the result should look like

#### Async Binder IPC (by Example)

- Binder allows for the asynchronous communication between the client and its service via the oneway declaration on the AIDL interface
- Of course, we still care about the result, so generally async calls are used with call-backs typically through listeners
- When clients provide a reference to themselves as call-back listeners, then the roles reverse at the time the listeners are called: clients' listeners become the services, and services become the clients to those listeners
- This is best explained via an example (based on Fibonacci)
- The code is available
  - As a ZIP archive: https://github.com/marakana/FibonacciAsyncBinderDemo/zipball/master
  - By Git: git clone https://github.com/marakana/FibonacciAsyncBinderDemo.git

# FibonacciCommon - Defining a oneway AIDL Service

• First, we need a listener, which itself is a oneway AIDL-defined "service":

FibonacciCommon/src/com/marakana/android/fibonaccicommon/IFibonacciServiceResponseListener.aidl:

```
package com.marakana.android.fibonaccicommon;

import com.marakana.android.fibonaccicommon.FibonacciRequest;
import com.marakana.android.fibonaccicommon.FibonacciResponse;

oneway interface IFibonacciServiceResponseListener {
   void onResponse(in FibonacciResponse response);
}
```

• Now we can create a our oneway (i.e. asynchronous) interface:

FibonacciCommon/src/com/marakana/android/fibonaccicommon/IFibonacciService.aidl:

```
package com.marakana.android.fibonaccicommon;

import com.marakana.android.fibonaccicommon.FibonacciRequest;
import com.marakana.android.fibonaccicommon.FibonacciResponse;
import com.marakana.android.fibonaccicommon.IFibonacciServiceResponseListener;

oneway interface IFibonacciService {
    void fib(in FibonacciRequest request, in IFibonacciServiceResponseListener listener);
}
```

# FibonacciService - Implementing our async AIDL service

• The implementation of our service invokes the listener, as opposed to returning a result:

FibonacciService/src/com/marakana/android/fibonacciservice/IFibonacciServiceImpl.java:

```
package com.marakana.android.fibonacciservice;
import android.os.RemoteException;
import android.os.SystemClock;
import android.util.Log;
import com.marakana.android.fibonaccicommon.FibonacciRequest;
import com.marakana.android.fibonaccicommon.FibonacciResponse;
import com.marakana.android.fibonaccicommon.IFibonacciService;
import com.marakana.android.fibonaccicommon.IFibonacciServiceResponseListener;
import com.marakana.android.fibonaccinative.FibLib;
public class IFibonacciServiceImpl extends IFibonacciService.Stub {
 private static final String TAG = "IFibonacciServiceImpl";
 @Override
 public void fib(FibonacciRequest request,
      IFibonacciServiceResponseListener listener) throws RemoteException {
    long n = request.getN();
   Log.d(TAG, "fib(" + n + ")");
    long timeInMillis = SystemClock.uptimeMillis();
```

```
long result;
switch (request.getType()) {
case ITERATIVE JAVA:
  result = FibLib.fibJI(n);
  break;
case RECURSIVE JAVA:
  result = FibLib.fibJR(n);
  break;
case ITERATIVE NATIVE:
  result = FibLib.fibNI(n);
  break;
case RECURSIVE NATIVE:
  result = FibLib.fibNR(n);
  break;
default:
  result = 0;
timeInMillis = SystemClock.uptimeMillis() - timeInMillis;
Log.d(TAG, String.format("Got fib(%d) = %d in %d ms", n, result,
    timeInMillis));
listener.onResponse(new FibonacciResponse(result, timeInMillis));
```

The service will not block waiting for the listener to return, because the listener itself is also oneway.

# FibonacciClient - Implementing our async AIDL client

• Finally, we implement our client, which itself has to also implement a listener as a Binder service:

FibonacciClient/src/com/marakana/android/fibonacciclient/FibonacciActivity.java:

```
package com.marakana.android.fibonacciclient;
import android.app.Activity;
import android.app.Dialog;
import android.app.ProgressDialog;
import android.content.ComponentName;
import android.content.Intent;
import android.content.ServiceConnection;
import android.os.Bundle;
import android.os.Handler;
import android.os.IBinder;
import android.os.Message;
import android.os.RemoteException;

  case R.id.type fib ji:
    type = FibonacciRequest.Type.ITERATIVE JAVA;
    break;
  case R.id.type fib nr:
    type = FibonacciRequest.Type.RECURSIVE NATIVE;
    break;
```

```
case R.id.type fib ni:
  type = FibonacciRequest.Type.ITERATIVE NATIVE;
  break;
default:
  return;
}
final FibonacciRequest request = new FibonacciRequest(n, type);
try {
  Log.d(TAG, "Submitting request...");
  long time = SystemClock.uptimeMillis();
  // submit the request; the response will come to responseListener
  this.service.fib(request, this.responseListener);
  time = SystemClock.uptimeMillis() - time;
  Log.d(TAG, "Submited request in " + time + " ms");
  // this dialog will be dismissed/removed by responseHandler
  super.showDialog(PROGRESS DIALOG ID);
} catch (RemoteException e) {
  Log.wtf(TAG, "Failed to communicate with the service", e);
```

Our listener should not retain a strong reference to the activity (and it does since it's an anonymous inner class), but in this case we skip on the correctness for the sake of brevity.

# Sharing Memory via Binder

- Binder transactional data is copied among parties communicating not ideal if we have a lot of data to send
  - o In fact, binder imposes limits on how much data we can send via transactions
- If the data we want to share comes from a file, then we should just send the file descriptor instead
  - o This is how we ask the media player to play an audio/video file for us we just send it the FD
- If the data we want to send is located in memory, rather than trying to send all of it at once, we could send multiple but smaller chunks instead
  - Complicates our design
- Alternatively, we could take advantage of Android's ashmem (Anonymous Shared Memory) facilities
  - Its Java wrapper android.os.MemoryFile is not meant for memory sharing from 3rd party apps
  - Drop to native (via JNI) and use ashmem directly?
- Native memory sharing implemented via frameworks/base/libs/binder/Parcel.cpp's:
  - o void Parcel::writeBlob(size\_t len, WritableBlob\* outBlob)

```
• status t Parcel::readBlob(size t len, ReadableBlob* outBlob)
```

• This is roughly implemented as follows:

Client

```
size_t len = 4096;
int fd = ashmem_create_region("Parcel Blob", len);
ashmem_set_prot_region(fd, PROT_READ | PROT_WRITE);
void* ptr = mmap(NULL, len, PROT_READ | PROT_WRITE, MAP_SHARED, fd, 0);
ashmem_set_prot_region(fd, PROT_READ);
writeFileDescriptor(fd, true);
// write into ptr for len as desired
...
munmap(ptr, len);
close(fd);
```

#### Service

```
int fd = readFileDescriptor();
void* ptr = mmap(NULL, len, PROT_READ, MAP_SHARED, fd, 0);
// read from ptr up to len as desired
...
munmap(ptr, len);
```

Removed error handling for brevity. Also, writeFileDescriptor (...) and readFileDescriptor (...) are provided by libbinder.

### Limitations of Binder

• Binder supports a maximum of 15 binder threads per process

frameworks/base/libs/binder/ProcessState.cpp

```
static int open_driver()
{
   int fd = open("/dev/binder", O_RDWR);
   if (fd >= 0) {
        ...
        size_t maxThreads = 15;
        result = ioctl(fd, BINDER_SET_MAX_THREADS, &maxThreads);
        ...
   } else {
        ...
   }
   return fd;
}
...
```

- Avoid blocking binder threads
- o If we need to perform a long-running task, it's better to spawn our own thread
- Binder limits its transactional buffer to 1Mb per process across all concurrent transactions

- o If arguments/return values are too large to fit into this buffer, TransactionTooLargeException is thrown
- Because this buffer is shared across all transactions in a given process, many moderately sized transactions could also exhaust its limit
- When this exception is thrown, we don't know whether we failed to *send the request*, or failed to *receive the response*
- Keep transaction data small or use shared memory (ashmem)

## Binder - Security

- Binder does directly deal with "security" concerns, but it enables a "trusted" execution environment and DAC
- The binder driver allows only a single CONTEXT\_MGR (i.e. servicemanager) to register:

drivers/staging/android/binder.c:

```
static long binder ioctl(struct file *filp, unsigned int cmd, unsigned long arg)
{
 switch (cmd) {
 case BINDER SET CONTEXT MGR:
   if (binder_context_mgr_node != NULL) {
      printk(KERN ERR "binder: BINDER SET CONTEXT MGR already set\n");
      ret = -EBUSY;
      goto err;
   binder context mgr node = binder new node(proc, NULL, NULL);
```

• The servicemanager in turn only allows registrations from trusted UIDs (like system, radio, media, etc.):

frameworks/base/cmds/servicemanager/service manager.c:

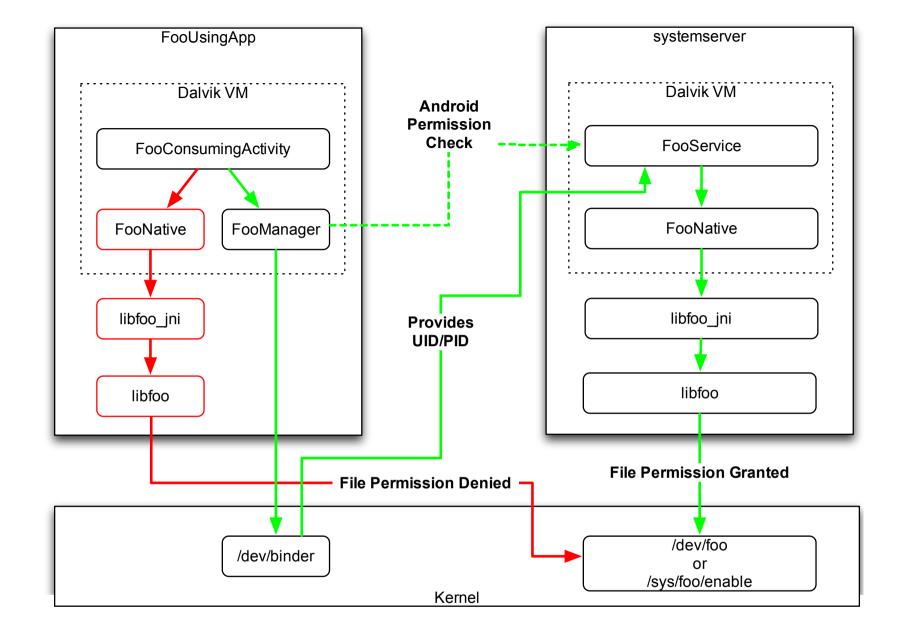

```
static struct {
   unsigned uid;
   const char *name;
} allowed[] = {
#ifdef LVMX
   { AID MEDIA, "com.lifevibes.mx.ipc" },
#endif
    { AID MEDIA, "media.audio flinger" },
    { AID MEDIA, "media.player" },
    { AID MEDIA, "media.camera" },
    { AID_MEDIA, "media.audio_policy" },
   { AID_DRM, "drm.drmManager" },
   { AID NFC, "nfc" },
    { AID RADIO, "radio.phone" },
   { AID RADIO, "radio.sms" },
    { AID RADIO, "radio.phonesubinfo" },
    { AID RADIO, "radio.simphonebook" },
/* TODO: remove after phone services are updated: */
    { AID RADIO, "phone" },
    { AID RADIO, "sip" },
    { AID RADIO, "isms" },
    { AID RADIO, "iphonesubinfo" },
    { AID RADIO, "simphonebook" },
};
int svc_can_register(unsigned uid, uint16 t *name)
```

```
unsigned n;
    if ((uid == 0) || (uid == AID SYSTEM))
        return 1;
    for (n = 0; n < sizeof(allowed) / sizeof(allowed[0]); n++)</pre>
        if ((uid == allowed[n].uid) && str16eq(name, allowed[n].name))
            return 1;
    return 0;
int do_add_service(struct binder_state *bs,
                   uint16 t *s, unsigned len,
                   void *ptr, unsigned uid)
{
    if (!svc_can_register(uid, s)) {
        LOGE("add_service('%s',%p) uid=%d - PERMISSION DENIED\n",
             str8(s), ptr, uid);
        return -1;
```

• Each binder transaction caries in it the UID and PID of the sender, which we can easily access:

```
• android.os.Binder.getCallingPid()
```

- android.os.Binder.getCallingUid()
- Once we have the knowledge of the calling UID, we can easily resolve it the calling app via PackageManager.getPackagesForUid(int uid)
- Once we have the knowledge of the calling app, we can easily check whether it holds a permission we want to enforce via PackageManager.getPackageInfo(String packageName, int flags) (with the PackageManager.GET PERMISSIONS flag)
- But, much easier to do permission enforcement via:
  - Context.checkCallingOrSelfPermission(String permission), which returns
    PackageManager.PERMISSION\_GRANTED if the calling process has been granted the permission or
    PackageManager.PERMISSION DENIED otherwise
  - Context.enforceCallingPermission(String permission, String message) to automatically throw SecurityException if the caller does not have the requested permission
- This is how many of the application framework services enforce their permissions

#### • For example:

frameworks/base/services/java/com/android/server/VibratorService.java:

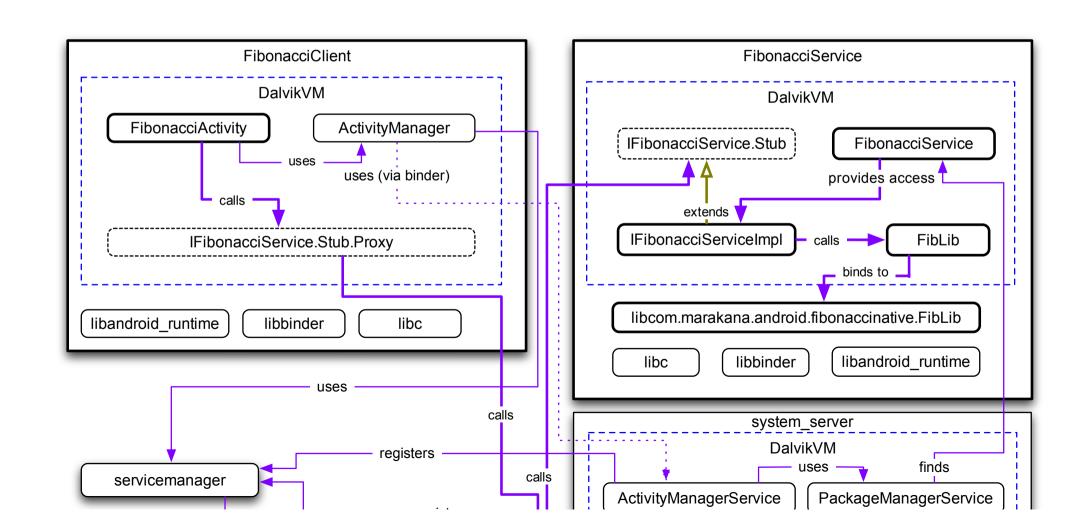

```
package com.android.server;
...
public class VibratorService extends IVibratorService.Stub {
    ...
    public void vibrate(long milliseconds, IBinder token) {
        if (mContext.checkCallingOrSelfPermission(android.Manifest.permission.VIBRATE)
        != PackageManager.PERMISSION_GRANTED) {
            throw new SecurityException("Requires VIBRATE permission");
        }
        ...
    }
    ...
}
```

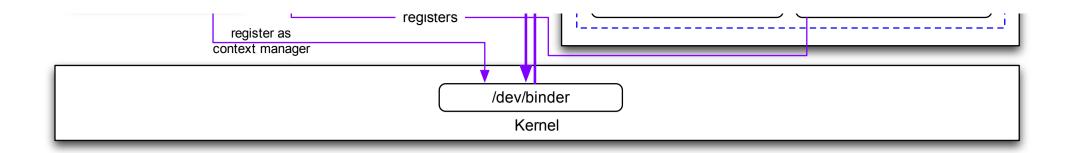

frameworks/base/services/java/com/android/server/LocationManagerService.java:

```
+ " requires ACCESS FINE LOCATION permission");
  if (LocationManager.NETWORK PROVIDER.equals(provider)
      && (mContext.checkCallingOrSelfPermission(ACCESS FINE LOCATION)
          != PackageManager.PERMISSION GRANTED)
      && (mContext.checkCallingOrSelfPermission(ACCESS COARSE LOCATION)
          != PackageManager.PERMISSION GRANTED)) {
      throw new SecurityException("Provider " + provider
              + " requires ACCESS FINE LOCATION or ACCESS COARSE LOCATION permission");
private Location _getLastKnownLocationLocked(String provider) {
  checkPermissionsSafe(provider);
public Location getLastKnownLocation(String provider) {
  _getLastKnownLocationLocked(provider);
```

### Permissions by Example

• In this example, we are given two applications, FibonacciClient and FibonacciService

- These two apps communicate via Binder/IPC
- Common files for these applications reside in a library project called FibonacciCommon
- The finished code for these applications (as Eclipse projects) is available:
  - As a ZIP archive: https://github.com/marakana/FibonacciBinderDemo/zipball/secured
  - By Git: git clone https://github.com/marakana/FibonacciBinderDemo.git -b secured

#### **Static Permission Enforcement**

Here, we want to restrict access to the com.marakana.android.fibonacciservice.FibonacciService to applications (i.e. clients) that hold *USE\_FIBONACCI\_SERVICE* custom permission

1. We start by by creating a custom permission group (making sure that we name-space it):

FibonacciService/res/values/strings.xml:

FibonacciService/AndroidManifest.xml:

This permission group is optional - as we could instead use one of the already provided groups

2. Next, we create a custom permission (again, making sure that we name-space it), while taking advantage of our newly-created permission group:

FibonacciService/res/values/strings.xml:

#### FibonacciService/AndroidManifest.xml:

3. Now we can statically require the permission on our FibonacciService service:

FibonacciService/AndroidManifest.xml:

4. If we now re-run the FibonacciService and re-run the FibonacciClient, we will notice that the client will fail to launch and adb logcat will show something like:

```
W/ActivityManager( 85): Permission Denial: Accessing service
ComponentInfo{com.marakana.android.fibonacciservice/com.marakana.android.fibonacciservice.FibonacciService}
from pid=540, uid=10043 requires com.marakana.android.fibonacciservice.USE FIBONACCI SERVICE
D/AndroidRuntime( 540): Shutting down VM
W/dalvikvm( 540): threadid=1: thread exiting with uncaught exception (group=0x409c01f8)
E/AndroidRuntime(
                  540): FATAL EXCEPTION: main
E/AndroidRuntime( 540): java.lang.RuntimeException: Unable to resume activity
{com.marakana.android.fibonacciclient/com.marakana.android.fibonacciclient.FibonacciActivity}:
java.lang.SecurityException: Not allowed to bind to service Intent {
act=com.marakana.android.fibonaccicommon.IFibonacciService }
E/AndroidRuntime( 540):
                            at android.app.ActivityThread.performResumeActivity(ActivityThread.java:2444)
E/AndroidRuntime(
                  540):
                            at dalvik.system.NativeStart.main(Native Method)
E/AndroidRuntime(
                  540): Caused by: java.lang.SecurityException: Not allowed to bind to service Intent {
act=com.marakana.android.fibonaccicommon.IFibonacciService }
E/AndroidRuntime(
                  540):
                            at android.app.ContextImpl.bindService(ContextImpl.java:1135)
E/AndroidRuntime(
                  540):
                            at android.content.ContextWrapper.bindService(ContextWrapper.java:370)
E/AndroidRuntime( 540):
                            at
com.marakana.android.fibonacciclient.FibonacciActivity.onResume(FibonacciActivity.java:65)
                            Force finishing activity com.marakana.android.fibonacciclient/.FibonacciActivity
W/ActivityManager(
                    85):
```

5. Finally, we can give FibonacciClient a fighting chance by allowing it to use the USE\_FIBONACCI\_SERVICE permission:

FibonacciClient/AndroidManifest.xml:

- 6. We can now observe that our client is again able to use the service
- 7. In the Emulator, if we go to  $Home \rightarrow Menu \rightarrow Manage\ apps \rightarrow Fibonacci\ Client \rightarrow PERMISSIONS$ , we should see the *Fibonacci Permissions* group and under it, *use fibonacci service* permission

### **Dynamic Permission Enforcement**

Here, we want to restrict access to the com.marakana.android.fibonacciservice.IFibonacciServiceImpl's recursive operations (fibJR(long n) and fibNR(long n)) for n > 10 to applications (i.e. clients) that hold USE SLOW FIBONACCI SERVICE custom permission

1. Like before, we start off by creating a custom permission:

FibonacciService/res/values/strings.xml:

FibonacciService/AndroidManifest.xml:

2. Next, we update our IFibonacciServiceImpl to enforce this permission dynamically - via a android.content.Context that get expect to get through the constructor:

FibonacciService/src/com/marakana/android/fibonacciservice/IFibonacciServiceImpl.java:

```
package com.marakana.android.fibonacciservice;
import android.content.Context;
public class IFibonacciServiceImpl extends IFibonacciService.Stub {
   private final Context context;
   public IFibonacciServiceImpl(Context context) {
        this.context = context;
    }
   private long checkN(long n) {
        if (n > 10) {
            this.context.enforceCallingOrSelfPermission(
                    Manifest.permission.USE SLOW FIBONACCI SERVICE, "Go away!");
        return n;
   public long fibJR(long n) {
        return FibLib.fibJR(this.checkN(n));
   public long fibNR(long n) {
        return FibLib.fibNR(this.checkN(n));
```

3. We have to update FibonacciService to invoke the new IFibonacciServiceImpl's constructor:

FibonacciService/src/com/marakana/android/fibonacciservice/FibonacciService.java:

4. If we now re-run the FibonacciService and re-run the FibonacciClient for a recursive operation with n > 10, we will notice that the client will fail and adb logcat will show something like:

```
...

D/IFibonacciServiceImpl( 617): fib(15, RECURSIVE_NATIVE)

D/IFibonacciServiceImpl( 617): fibNR(15)

W/dalvikvm( 604): threadid=11: thread exiting with uncaught exception (group=0x409c01f8)

E/AndroidRuntime( 604): FATAL EXCEPTION: AsyncTask #1

E/AndroidRuntime( 604): java.lang.RuntimeException: An error occured while executing doInBackground()

...

E/AndroidRuntime( 604): at java.lang.Thread.run(Thread.java:856)

E/AndroidRuntime( 604): Caused by: java.lang.SecurityException: Go away!: Neither user 10043 nor current process has com.marakana.android.fibonacciservice.USE_SLOW_FIBONACCI_SERVICE.

...
```

5. Finally, we can allow FibonacciClient to melt our CPU and drain our battery by allowing it to use the USE SLOW FIBONACCI SERVICE permission:

FibonacciClient/AndroidManifest.xml:

- 6. We can now observe that our client is again able to use recursive fibonacci operations even for n > 10
- 7. In the Emulator, if we go to  $Home \rightarrow Menu \rightarrow Manage\ apps \rightarrow Fibonacci\ Client \rightarrow PERMISSIONS \rightarrow$  Fibonacci Permissions, we should see both use fibonacci service and use slow fibonacci service operations permissions

### Other Binder Features

- Given a reference to an IBinder object, we can:
  - Ask whether the remote object is alive, via isBinderAlive() and pingBinder()
  - Ask to be notified of its death, via linkToDeath (IBinder.DeathRecipient recipient, int flags):

frameworks/base/services/java/com/android/server/LocationManagerService.java:

```
public class LocationManagerService extends ILocationManager.Stub implements Runnable {
  private Receiver getReceiver(ILocationListener listener) {
    IBinder binder = listener.asBinder();
    Receiver receiver = mReceivers.get(binder);
    if (receiver == null) {
      receiver = new Receiver(listener);
      receiver.getListener().asBinder().linkToDeath(receiver, 0);
   return receiver;
  private final class Receiver implements IBinder.DeathRecipient, PendingIntent.OnFinished {
   final ILocationListener mListener;
    Receiver(ILocationListener listener) {
      mListener = listener;
    public void binderDied() {
      removeUpdatesLocked(this);
```

- Binder driver reports various stats on active/failed transactions via /proc/binder/
  - o /proc/binder/failed\_transaction\_log
  - o /proc/binder/state
  - o /proc/binder/stats
  - o /proc/binder/transaction\_log
  - o /proc/binder/transactions
  - o /proc/binder/proc/<pid>

## Summary

#### We learned about:

- Why Android needs IPC
- What is Binder and how it differs from other forms of IPC
- Binder vs Intent/ContentProvider/Messenger-based IPC
- Binder Terminology
- Binder Communication and Discovery Model
- AIDL
- Binder Object Reference Mapping
- Synchronous vs Async Binder Invocations
- Memory Sharing
- Binder Limitations
- Security Implications
